STEP 01 | Project Overview & Problem Definition

Establish why the system is needed, what success means, and which current support problems it will address.

1. Objective

- Design a Salesforce-based system that predicts support-ticket priority from case details and routes each case to an appropriate agent or queue.
- Use Salesforce Flow for deterministic automation and Agentforce or another approved Salesforce AI capability for text analysis.
- Improve response speed, routing consistency, workload visibility, and customer experience.

2. Problem to solve

- Manual triage can delay urgent tickets.
- Priority decisions may vary between agents.
- Cases can be assigned to teams without the required skills.
- Workloads can become uneven and SLA risks may be noticed too late.
- Managers may lack a single view of backlog, priority, and routing performance.

3. Proposed solution at a glance

- Capture support requests as Salesforce Cases.
- Analyze the description and related context for issue type, impact, and urgency indicators.
- Apply approved priority rules and decide whether human review is needed.
- Route to a qualified agent or queue using documented criteria.
- Track the outcome through reports, dashboards, and feedback.

4. Initial assumptions

- The organization has or plans to use Salesforce Service Cloud.
- Support priority definitions, SLA rules, and assignment policies can be documented.
- Required Agentforce/AI capabilities and licenses will be verified in the target Salesforce org.
- AI recommendations will not replace explicit business rules or authorized human overrides.

5. Deliverables

- Approved requirements and project scope.
- Proposed Salesforce architecture and data model.
- Flow and AI design, routing rules, and exception handling.
- Test plan, dashboard plan, rollout plan, and operational guidance.
