STEP 08 | Salesforce Flow & Agentforce Implementation Plan

Turn the architecture into an implementation sequence while leaving org-specific setup to be validated.

1. Prepare the Salesforce environment

- Use a development or sandbox org for configuration and testing.
- Confirm object permissions, queues, users, field requirements, and required AI entitlements.
- Document the priority rubric and routing policy before building automation.

2. Configure Case fields and queues

- Reuse standard Case fields where possible.
- Create approved custom fields for AI recommendation, review state, routing reason, and timestamps.
- Create or verify queues for general triage, specialist teams, and human review.
- Set field-level security and permissions.

3. Design the Flow

- Choose record-triggered Flow on Case creation or on relevant field changes, with entry criteria to avoid repeated processing.
- Validate required data and set an initial safe state.
- Invoke the approved AI action using only necessary fields.
- Validate output values and apply priority decision logic.
- Route to an agent/queue or review queue.
- Update status/audit fields and send approved notifications.
- Add fault paths and ensure the Case remains available if analysis fails.

4. Design the Agentforce/AI action

- Define a narrow task: summarize the issue, identify issue category, extract impact/urgency signals, and recommend a priority.
- Specify allowed output values and a strict structured response format.
- Tell the model not to invent facts and to mark ambiguity for review.
- Treat case descriptions as untrusted content; ignore embedded instructions unrelated to triage.
- Test with representative cases before connecting to production routing.

5. Routing logic

- Use explicit rules for critical incidents and SLA escalation.
- Match category/product/language/skill to eligible queues or agents.
- Use availability/capacity only where supported and configured.
- Use a fallback queue if no eligible owner is found.
- Allow authorized override and record the routing reason.

6. Build safeguards

- Add fault handling for AI/action failures.
- Prevent recursive updates from retriggering triage unnecessarily.
- Consider asynchronous processing if the workflow or latency requirements call for it.
- Log errors without exposing sensitive customer content unnecessarily.

7. Build checklist

- Fields and queues configured.
- Flow entry criteria and fault paths tested.
- AI output schema validated.
- Priority rules approved by business owner.
- Routing and fallback verified.
- Permissions reviewed.

Project note: This is a proposed implementation guide. Validate Salesforce features, licensing, configuration, security requirements, and business policies in the target organization before implementation.
